

Generic Graph Layer Projection from RDF to Structured Property Graph

What?
Definition and the extraction of a well defined subset of nodes and edges from a larger context gives us a repeatable procedure for information projection.

How?
A SPARQL query provides nodes and links from the RDF graph in such a way, that layers of a multi-layer network are defined by the result of the query.

Why?
Integration of multiple domain specific ontologies should be left out of the graph data modeling process. This simplifies the analytical work on the well defined time dependent multi-layer networks.
